### **Abundant Number**

An abundant number is a number for which the sum of its proper divisors is greater than the number itself. Proper divisors of the number are those that are strictly lesser than the number.

### **Input Format:**

Take input an integer from stdin

#### **Output Format:**

Return Yes if given number is Abundant. Otherwise, print No

### **Example input:**

12

#### **Output:**

Yes

Explanation

The proper divisors of 12 are: 1, 2, 3, 4, 6, whose sum is 1 + 2 + 3 + 4 + 6 = 16. Since sum of proper divisors is greater than the given number, 12 is an abundant number.

### **Example input:**

13

### **Output**:

No

### **Explanation**

The proper divisors of 13 is: 1, whose sum is 1. Since sum of proper divisors is not greater than the given number, 13 is not an abundant number.

For example:

Test Result print(abundant(12)) Yes print(abundant(13)) No

## Program:

```
def abundant(n):
```

```
l,s=[],0
for i in range(1,int(n//2)+1):
    if(n%i==0):
```

```
l.append(i)
for i in l:
    s+=i
if(s>n):
    return("Yes")
else:
    return("No")
```

### Automorphic number or not

An automorphic number is a number whose square ends with the number itself. For example, 5 is an automorphic number because 5\*5=25. The last digit is 5 which same as the given number.

If the number is not valid, it should display "Invalid input". If it is an automorphic number display "Automorphic" else display "Not Automorphic".

Input Format:

Take a Integer from Stdin

Output Format:

Print Automorphic if given number is Automorphic number, otherwise Not Automorphic

Example input: 5 Output: Automorphic Example input: 25 Output: Automorphic

Example input: 7 Output: Not Automorphic

For example:

Test Result

## Program:

```
def automorphic(n):
    a=str(n*n)
    if(int(a[-1])==n):
        return("Automorphic")
    else:
        return("Not Automorphic")
```

	Test	Expected	Got	
~	<pre>print(automorphic(5))</pre>	Automorphic	Automorphic	~
<b>~</b>	<pre>print(automorphic(7))</pre>	Not Automorphic	Not Automorphic	~

Check Product of Digits							
	Trite a code to check whether product of digits at even places is divisible by sum digits at odd place of a positive integer.  Input Format:						
Take an input intege	r from stdi	n.					
Output Format:							
Print TRUE or FALS	E.						
Example Input:							
1256							
Output:							
TRUE							
Example Input:							
1595							
Output:							
FALSE							
For example:							
Test	Result						
print(productDigits(1256	)) True						

# Program:

def productDigits(n):

print(productDigits(1595)) False

```
a=str(n)
s,p=0,1
for i in range(0,len(a),2):
    s+=int(a[i])
for i in range(1,len(a),2):
    p*=int(a[i])
if(p%s==0):
    return("True")
else:
    return("False")
```

### **Christmas Discount**

An e-commerce company plans to give their customers a special discount for Christmas.

They are planning to offer a flat discount. The discount value is calculated as the sum of all the prime digits in the total bill amount.

Write an python code to find the discount value for the given total bill amount.

#### **Constraints**

 $1 \le \text{orderValue} \le 10 \mathrm{e}^{100000}$ 

Input

The input consists of an integer orderValue, representing the total bill amount.

Output

Print an integer representing the discount value for the given total bill amount.

Example Input

578

Output

12

#### For example:

Test	Result
print(christmasDiscount(578))	12

## Program:

def christmasDiscount(n):

```
res=0
while n!=0:
rem=n%10
flag=0
for i in range(1,rem+1):
if rem%i==0:
```

```
flag+=1
if flag==2:
res=res+rem
n=n//10
```

return res

Ex. No. : 7.5 Date: Name: Register No.: Coin Change complete function to implement coin change making problem i.e. finding the minimum number of coins of certain denominations that add up to given amount of money. The only available coins are of values 1, 2, 3, 4 Input Format: Integer input from stdin. Output Format: return the minimum number of coins required to meet the given target. Example Input: 16 Output: 4 Explanation: We need only 4 coins of value 4 each Example Input: 25 Output: 7 Explanation: We need 6 coins of 4 value, and 1 coin of 1 value Program: def coinChange(amount):

# Available coin denominations

```
coins = [1, 2, 3, 4]
```

# Initialize a list to store the minimum number of coins for each amount from 0 to the target amount

```
dp = [float('inf')] * (amount + 1)
```

```
dp[0] = 0 # Base case: 0 coins needed to make amount 0
  # Iterate through all amounts from 1 to the target amount
  for i in range(1, amount + 1):
    # Iterate through all available coin denominations
    for coin in coins:
     # If the current coin denomination is less than or equal to the
current amount
     if coin <= i:
            # Update dp[i] to be the minimum between its current value
and dp[i - coin] + 1
            dp[i] = min(dp[i], dp[i - coin] + 1)
  # The result is stored at dp[amount]
  return dp[amount]
  amount = int(input())
  print(coinChange(amount))
```

### **Difference Sum**

Given a number with maximum of 100 digits as input, find the difference between the sum of odd and even position digits.

Input Format:

Take a number in the form of String from stdin.

Output Format:

Print the difference between sum of even and odd digits

Example input:

1453

Output:

1

Explanation:

Here, sum of even digits is 4 + 3 = 7

sum of odd digits is 1 + 5 = 6.

Difference is 1.

Note that we are always taking absolute difference

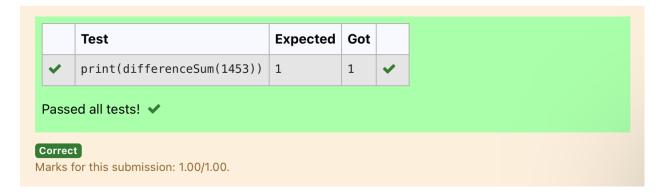

## Program:

s=sum(b)

```
def differenceSum(n):
```

```
a=[]
b=[]
k=str(n)
for i in range(len(k)):
    if int(i)%2==0:
        a.append(int(k[i]))
    else:
        b.append(int(k[i]))
```

```
r=sum(a)
j=s-r
return j
```

### Ugly number

A number is considered to be ugly if its only prime factors are 2, 3 or 5. [1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 15, ...] is the sequence of ugly numbers.

Task:

complete the function which takes a number n as input and checks if it's an ugly number. return ugly if it is ugly, else return not ugly

Hint:

An ugly number U can be expressed as:  $U = 2^a * 3^b * 5^c$ , where a, b and c are nonnegative integers.

### For example:

Test	Result	
print(checkUgly(6))	ugly	
print(checkUgly(21))	not ugly	

# Program:

```
def checkUgly(n):
```

```
for i in range(n):
    for j in range(n):
        if (n==(2**i)+(3**j)+(5**k)):
            return("ugly")
    return("not ugly")
```

	Test	Expected	Got	
~	<pre>print(checkUgly(6))</pre>	ugly	ugly	~
~	<pre>print(checkUgly(21))</pre>	not ugly	not ugly	~
